(54) Title: INHIBITORY IMMUNOGLOBULIN POLYPEPTIDES TO HUMAN PDGF BETA RECEPTOR

(57) Abstract

The present invention is directed towards immunoglobulin polypeptides that specifically bind to the extracellular domain of the human type beta PDGF receptor. The binding of the immunoglobulin polypeptides to the receptor inhibits PDGF-induced (or stimulated) receptor activation as indicated by inhibition of receptor phosphorylation and dimerisation, and by inhibition of PDGF-mediated mitogenesis, chemotaxis and migration of cells displaying the human PDGF type beta receptor on the cell surface. Nucleic acids encoding the immunoglobulin polypeptides are also included in the invention. The immunoglobulin polypeptides have diagnostic and therapeutic uses.

INHIBITORY IMMUNOGLOBULIN POLYPEPTIDES
TO HUMAN PDGF BETA RECEPTOR

FIELD OF THE INVENTION

The present invention relates generally to the production and use of immunoglobulin polypeptides that inhibit PDGF-mediated proliferation of cells displaying the human type beta platelet derived growth factor receptor.

BACKGROUND OF THE INVENTION

Platelet derived growth factor (PDGF) is a potent proliferative agent in cells of mesenchymal origin (Antoniades, H.N. et al. (1979) Proc. Natl. Acad. Sci. USA 76: 1809-1813; Bowen-Pope, D.F. and Ross, R. (1982) J. Biol. Chem. 257: 5161-5171; Heldin, C-H. et al. (1983) J. Biol. Chem. 258: 10054-10059, all of which are incorporated herein by reference). PDGF (M.W. 30 KDa) is a disulphide-linked dimer consisting of 2 homologous chains termed A or B (Johnsson, A. et al. (1982) Biochim. Biophys. Res. Commun. 104: 66-74, which is incorporated herein by reference). The chains may combine with chains of the same or the other type, resulting in 3 isoforms AA, BB or AB (Heldin, C-H. et al. (1986) Nature 319: 511-514, which is incorporated herein by reference). The mitogen PDGF was first identified (Antoniades, H.N. (1979) Proc. Natl. Acad. Sci. USA 76: 1809-1813; Raines, E.W. and Ross, R. (1982) J. Biol. Chem. 257: 5154-5160, both of which are incorporated herein by reference) and purified from human platelets (Raines, op. cit.), though subsequent research has shown that several cell types including vascular endothelial cells, vascular smooth muscle cells, macrophages and even fibroblasts synthesise PDGF (Ross, R. et al. (1986) Cell 46: 155-169, which is incorporated herein by reference).

The cellular proliferation induced by all isoforms of PDGF is mediated by ligand binding to the PDGF receptor (Heldin, C-H. (1983) op. cit., Ek, B. et al. (1982) Nature 295:

419-420; Glenn, K. et al. (1982) J. Biol. Chem. 257:
5172-5176; Frackelton, A.R. et al. (1984) J. Biol. Chem. 259:
7909-7915; Williams, L.T. et al. (1984) J. Biol. Chem. 259:
5287-5294, all of which are incorporated herein by reference).
The PDGF receptor (M.W. 180 KDa) belongs to the tyrosine kinase
family and consists of two receptor subtypes, termed type A (or
type alpha) (Matsui, T. et al. (1989) Science 243: 800-804, and
Claesson-Welsh, L. (1989) Proc. Natl. Acad. Sci. USA 86:
4917-4921, both of which are incorporated herein by reference)
and type B (or type beta) (Yarden, Y. et al. (1986) Nature 323:
226-232, and Escobedo, J.A. et al. (1988) Science 240:
1532-1534, both of which are incorporated herein by reference).

High affinity binding of PDGF to the receptor is
followed by receptor dimerisation (Bishayee, S. et al. (1989)
J. Biol. Chem. 264: 11699-11705, and Heldin, C-H. et al. (1989)
J. Biol. Chem. 264: 8905-8912) and autophosphorylation
(Frackelton, et al. op. cit.), and results in a complicated
series of intracellular signalling events culminating in DNA
synthesis. Mouse and human PDGF beta receptor and PDGF alpha
receptor genes have been cloned (Matsui et al. op. cit.,
Claesson-Welsh et al. op. cit., Yarden et al. op. cit., and
Escobedo et al. op. cit.). When referring to PDGF receptors
herein, type A and type alpha are used interchangeably, as are
type B and type beta.

The two receptor isoforms may be distinguished by their
markedly different ligand binding specificities. PDGF beta
receptor binds only B-chain (isoforms BB and AB), while PDGF
alpha receptor can bind all forms of PDGF (isoforms containing
A and/or B chain (Matsui et al. op. cit., Claesson-Welsh et al.
op. cit., and Seifert, R.A. et al. (1989) J. Biol. Chem. 264:
8771-8778). The PDGF receptor shows a high degree of
structural homology to the macrophage-colony stimulating factor
receptor (Coussens, L. et al. (1986) Nature 320: 277-280) and
the c-kit protooncogene product (Yarden, et al., op. cit.).

The PDGF receptors are characterised by an
extracellular domain which may be demarcated into five Ig-like
domains (Domains 1-5) based on their β-sheet rich structure.

3

These Ig repeats of approximately 100 amino acids each have regularly spaced cysteine residues (except in the fourth repeat). The receptor has a single transmembrane domain and a cytoplasmic tyrosine kinase domain (Williams, L. T. (1989) _Science_ 243: 1564-1570, which is incorporated herein by reference).

PDGF plays an important role during normal physiological processes such as tissue repair and embryogenesis (Ross, R. et al. _op. cit._). However, studies now implicate this potent mitogen in pathological proliferative disorders and in the development of certain carcinomas (Ross, R. et al. _op. cit._). Expression of PDGF A chain and PDGF beta receptor has been detected in human atherosclerotic plaques by _in situ_ hybridisation (Wilcox, J.N. et al. (1988) _J. Clin. Invest._ 82: 1134-1143). Recently, Ferns et al. ((1991) _Science_ 253: 1129-1132) have reported that a polyclonal antibody to PDGF significantly reduced the formation of intimal lesions in deendothelialised carotid arteries of athymic nude rats. PDGF has been implicated in the pathology of proliferative diseases in cells of mesenchymal origin (Nister, M. et al. (1984) _Proc. Natl. Acad. Sci. USA_ 81: 926-930, and Nister, M. et al. (1987) _Cancer Res._ 47: 4953-4961, both of which are incorporated herein by reference). Golden et al. have reported that PDGF A chain message was increased in areas of intimal hyperplasia in a baboon model for vascular grafts ((1990) _J. Vasc. Surg._ 11: 580-585). PDGF is also chemotactic for smooth muscle (Westermark, B. et al. (1990) _Proc. Natl. Acad. Sci. USA_ 87: 128-132), and platelet PDGF may be the causative agent for the migration and proliferation of smooth muscle cells in the ballooned rat carotid artery, which results in significant stenosis.

The study of other growth factors and their receptors has been aided by the invention of antibodies against the receptors. For example, antibodies that recognize the epidermal growth factor receptor have proved to be powerful tools in evaluating the mechanism of receptor activation (Spaargaren, M. et al. (1991) _J. Biol. Chem._ 266: 1733-1739,

4

which is incorporated herein by reference). Antibodies against receptors for interleukin-2 (IL-2) inhibit IL-2 internalisation, and thus inhibit the subsequent induction of proliferation of responsive cells (Duprez, V. et al. (1991) J. Biol. Chem. 1497-1501, which is incorporated herein by reference). Similarly, a monoclonal antibody against the epidermal growth factor (EGF) receptor inhibits estrogen-stimulated growth of the human mammary adenocarcinoma cell line MCF-7 (Eppstein, D.A. (1989) J. Cell. Physiol. 141: 420-430, which is incorporated herein by reference). Such antibodies may be of great therapeutic value in treating growth factor-mediated diseases.

Several groups have isolated antibodies against PDGF receptors, but these antibodies have limited utility (see, for example, Kawahara, R.S. et al. (1987) Biochem. Biophys. Res. Commun. 147: 839-845, which is incorporated herein by reference). Additional monoclonal antibodies have been raised against the extracellular PDGF-binding domain of a PDGF receptor from porcine uterus (Ronnestrand, L. and Terracio, L. (1988) J. Biol. Chem. 263: 10429-10435, which is incorporated herein by reference), but these antibodies did not inhibit binding of ^{125}I-labelled PDGF to human fibroblasts. Numerous antibodies against a PDGF receptor that did not inhibit PDGF activity have also been reported by Kanakaraj, P.S. et al. (1991) Biochemistry 30: 1761-1767; Claesson-Welsh, L. et al. (1989) J. Biol. Chem. 264: 1742-1747; Seifert, R. A. et al. (1989) J. Biol. Chem. 264: 8771-8778; Kumjian, D. A. et al. (1989) Proc. Natl. Acad. Sci. USA 86: 8232-8236; Bishayee, S. et al. (1988) Mol. Cell. Biol. 8: 3696-3702; Hart, C. E. et al. (1987) J. Biol. Chem. 262: 10780-10785; Escobedo, J. A. et al. (1988) J. Biol. Chem. 263: 1482-1487; Daniel, T. O. et al. (1987) J. Biol. Chem. 262: 9778-9784; Keating, M. T. and L. T. Williams (1987) J. Biol. Chem. 262: 7932-7937; Kazlauskas, A. and J. A. Copper (1990) EMBO J. 9: 3279-3286; all of which are incorporated herein by reference.

Thus, there exists a need for immunoglobulin and other agents capable of specifically inhibiting activation of the

human receptor and/or proliferation of cells displaying the
human type beta PDGF receptor. Such agents would be useful in
mapping the different functional domains of the receptor, and
in dissecting the role of PDGF and its receptors in normal and
disease processes. Furthermore, such agents will have
therapeutic value in the treatment of PDGF-mediated
proliferative diseases, and also diseases involving PDGF-
mediated chemotaxis and migration. Such diseases include:
        a)   restenosis, including coronary restenosis after
angioplasty, atherectomy, or other invasive methods of plaque
removal, and renal or peripheral artery restenosis after the
same procedures;
        b)   vascular proliferative phenomena and fibrosis
associated with other forms of acute injury such as: pulmonary
fibrosis associated with adult respiratory distress syndrome,
renal fibrosis associated with nephritis, coronary stenosis
associated with Kawasake's disease, and vascular narrowings
associated with other arteritides such as Takayasha's disease;
        c)   prevention of narrowings in vein grafts;
        d)   prevention of narrowings due to accelerated smooth
muscle cell migration and proliferation in transplanted organs;
        e)   other fibrotic processes, such as schleroderma,
myofibrosis; and
        f)   inhibition of tumor cell proliferation which is
mediated by PDGF.
        The present invention fulfills these and other needs.

SUMMARY OF THE INVENTION

        The present invention provides immunoglobulin
polypeptides that specifically bind to a human type beta
platelet derived growth factor receptor (βPDGF-R), wherein
binding of the immunoglobulin polypeptide to the fifth Ig-like
domain of a human βPDGF-R has one or more of the following
effects: i) inhibition of PDGF BB binding to the receptor; ii)
inhibition of PDGF-induced βPDGF-R phosphorylation; iii)
inhibition of PDGF-induced dimerization of βPDGF-R; iv)
inhibition of PDGF-induced mitogenesis of cells displaying

6

human βPDGF-R; and v) PDGF-induced chemotaxis and migration of cells displaying βPDGF-R. A preferred embodiment of the invention is a monoclonal antibody, such as the monoclonal antibody 2A1E2, which is of the IgG₁ isotype.

Isolated nucleic acids having a sequence substantially identical to those coding for all or part of an immunoglobulin polypeptide having the described properties are also included in the invention. A cell line transfected, transformed, or infected with these nucleic acids is another embodiment of the invention, as is a method of producing the immunoglobulin polypeptide or fragments thereof by growing a cell line containing the claimed nucleic acids and harvesting the immunoglobulin polypeptides or fragments.

The immunoglobulin polypeptides of the invention have diagnostic as well as therapeutic uses. For example, a further aspect of the invention involves methods of treating a human having a PDGF-mediated disease involving proliferation of smooth muscle cells, comprising administering to the patient a therapeutically effective dose of an immunoglobulin polypeptide of the present invention.

BRIEF DESCRIPTION OF THE FIGURES

Fig 1. Recombinant Human Beta Receptor Extracellular Domain Constructs. Deletion mutagenesis of the full length PDGF beta receptor was performed as described in Methods. PΔ1 refers to the 5 domain extracellular PDGF beta receptor (amino acids 1-499) which was made by deleting, from the PDGF type beta receptor cDNA, the codons for amino acid residues 500-1074 using the oligonucleotide GTG TGA GGA ACG GGA AAT TCA TCG AAG GAC ATC CCC CGAC (SEQ ID NO:1). PΔ2 refers to the 4 domain extracellular PDGF receptor (aa 1-384) which was made by deleting the conds for amino acid residues 385-1074 from the cDNA, using the oligonucleotide GGA AGG TCG ATG TCT AGT TAA TCG AAG GAC ATC CCC CGAC (SEQ ID NO:2). Putative Ig domains are indicated as follows: D1 (aa 1-91), D2 (aa 92-181), D3 (aa 182-282), D4 (aa 283-384) and D5 (aa 385-499). The peptide determinant of the polyclonal antisera 1-3-5 is indicated above D1.

Fig 2.   A. Western Blot of Secreted 5 Domain
Extracellular PDGF Beta Receptor pΔ1-5.   Reduced (Lanes 1-3)
and non-reduced (Lanes 4-6) secreted extracellular domain of
PDGF beta receptor (PΔ1-5, 5 μg/lane) was electrophoresed on 7%

5   Laemmli gels, followed by Western transfer as described in
Methods. The nitrocellulose was blocked in phosphate-buffered
saline (PBS) containing 2% milk, cut into strips and incubated
overnight at 4°C with 60 μg/ml of either MAb 2A1E2 (Lanes 1 and
4), another PDGF beta receptor monoclonal antibody (1C7D5)

10   (Lanes 2 and 5), or a non-specific monoclonal antibody (Lanes 3
and 6). The nitrocellulose strips were washed with PBS
containing 0.5% milk and 0.1% Tween 20, incubated with
^{125}I-labelled protein A for 2 hours at room temperature, and
exposed to X-ray film. The arrow indicates the position of

15   pΔ1-5.

B.   Immunoprecipitation of Secreted 4 Domain
Extracellular PDGF Beta Receptor pΔ2-7. Secreted 4 domain
extracellular PDGF beta receptor pΔ2-7 (2.6 μg) was incubated
with either MAb 2A1E2 (Lane 2, 5 μg), 1C7D5 (Lane 3, 5 μg) or

20   nonspecific MAb (Lane 4, 5 μg) in a final volume of 500 μl in
I.P. buffer for 3 hours at 4°C. Protein A sepharose CL4B:
Protein G sepharose CL4B (1:1) was added to each tube (60 μl of
50% slurry) and the incubation was continued for 2 hours at
4°C. The beads were spun down, washed 5X in I.P. buffer and

25   electrophoresed on a 10% Laemmli gel. The gel was transferred
onto nitrocellulose and blocked in PBS containing 5% milk. The
blot was incubated with a 1:100 dilution of a rabbit polyclonal
anti-PDGF beta receptor Ab (1-3-5) in PBS containing 0.5% milk.
After incubating overnight, the blot was washed, incubated with

30   ^{125}I-Protein A, washed, and exposed to X-ray film. Lane 1 shows
a standard of PΔ2-7 without immunoprecipation. The arrow
indicates the position of pΔ2-7.

C.   Immunoprecipitation of Secreted Extracellular PDGF
Beta Receptor by MAb 2A1E2. Extracellular human PDGF beta

35   receptor (pΔ1-5, 5 μg) was immunoprecipitated with 5 μg of
either nonspecific MAb (Lane 2), MAb 2A1E2 (Lane 3), or 1C7D5
(Lane 4), as described for panel A. The samples were were

8

processed and the blot was incubated with rabbit polyclonal anti-PDGF beta receptor 1-3-5 (1:100 dilution) and ^{125}I-protein A, as described in the legend for Panel B. Lane 1 contains 5 μg of standard pΔ1-5.

5   Fig 3.   Inhibition of ^{125}I-PDGF BB Binding to HR5 Cells. A) HR5 cells were incubated with various concentrations of MAb 2A1E2 or control MAbs (200 nM anti-IIb/IIIa or 200 nM 4C5C8) as described in Methods. The cells were then incubated with ^{125}I-PDGF BB and the bound
10 radioactivity was determined as described. Non-specific binding is defined as the amount of ^{125}I-PDGF BB bound in the presence of 100-fold excess unlabelled PDGF BB. B) HR5 cells were incubated with various concentrations of full-length MAb 2A1E2, MAb 2A1E2-F(ab')2, or MAb 2A1E2-Fab, and 100 nM
15 full-length anti-IIb/IIIa as described in Methods. Total binding of ^{125}I-PDGF BB to the cells in the presence and absence of MAbs and their derivatives was measured. The amount of ^{125}I-PDGF BB bound in the presence of 100 fold-excess unlabelled PDGF BB represents non-specific binding.

20   Fig 4.   Inhibition of Phosphorylation of HR5 cells by MAb 2A1E2. Confluent monolayers of HR5 cells in 6-well dishes were preincubated in duplicate with various MAbs, followed by incubation with ligand PDGF BB as described in Methods. Cells were solubilised, and the equivalent of one 6-well dish was
25 electrophoresed on a 7% Laemmli gel and transferred onto nitrocellulose. The western blot was blocked and then incubated with antiphosphotyrosine MAb. The blot was then incubated with ^{125}I-Protein A and autoradiographed. Lanes 3-7 represent wells which were preincubated with either 0.13 nM MAb
30 2A1E2 (Lane 3), 1.3 nM MAb 2A1E2 (Lane 4), 13.3 nM MAb 2A1E2 (Lane 5), 0.13 μM MAb 2A1E2 (Lane 6) or 0.53 μM MAb 2A1E2 (Lane 7), followed by 100 ng/ml PDGF BB. Lane 2 shows the degree of phosphorylation in the presence of 100 ng/ml PDGF BB, when the cells were first preincubated with 0.53 μM of a non-specific
35 MAb, and Lane 8 shows PDGF BB-induced phosphorylation when cells are preincubated with 0.53 μM of PDGF beta receptor MAb

4C5C8. The arrow indicates the position of the full length
human PDGF beta receptor.

        Fig 5.   Inhibition of PDGF BB-Mediated Dimerisation
of PDGF receptor by MAb 2A1E2. HR5 cells were incubated with
5   either 13 nM MAb 2A1E2 (Lane 3), 0.13 μM MAb 2A1E2 (Lane 4),
or 1.3 μM MAb 2A1E2 (Lane 5), followed by 100 ng/ml PDGF BB,
and cross-linking was carried out as described in Methods.
Lane 6 represents the effect of 0.1 μM anti-IIb/IIIa MAb on
dimerisation. Lane 1 shows the relative amount of dimer in the
10   absence of added crosslinker and lane 2 shows the amount of
dimerized PDGF receptor in the absence of antibody.

        Fig 6.   Inhibition of Mitogenesis in AG01523B cells
by MAb 2A1E2. Cells were grown to confluence and incubated as
described in Methods with various concentrations of either MAb
15   2A1E2 (open circles) or non-inhibitory control PDGF beta
receptor MAb 4C5C8 (solid squares) in the presence of 50 ng/ml
of PDGF BB. ^{3}H-thymidine incorporation was measured as
described.

        Fig 7.   Inhibition of Phosphorylation by MAb 2A1E2 in
20   Baboon Smooth Muscle Cells. Baboon smooth muscle cells were
incubated with no PDGF BB (Lane 1), or with 100 ng/mL PDGF BB
in the absence of MAb (Lane 2), or in the presence of 2 nM MAb
2A1E2 (Lane 3), 200 nM MAb 2A1E2 (Lane 4) or 20 nM MAb 2A1E2
(Lane 5). Ligand induced phosphorylation was determined by
25   Western analysis, as described in Methods.

        Fig 8.   Inhibition of Mitogenesis by MAb 2A1E2 in
Baboon Smooth Muscle Cells. Confluent baboon smooth muscle
cells were incubated with 1 nM, 5 nM, 25 nM, 250 nM, or 1 μM
MAb 2A1E2 in the presence of various concentrations of PDGF BB.
30   ^{3}H-Thymidine incorporation was measured as described in
Methods. Data is expressed as a percent of maximal
^{3}H-thymidine incorporated (approximately 30-50000 cpm) at
saturating ligand concentration (10 ng/ml) in the absence of
MAb. ^{3}H-Thymidine incorporation in the absence of PDGF BB is
35   5-8000 cpm. The graph represents the average of 4 separate
experiments.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention provides an immunoglobulin polypeptide that specifically binds to the human type beta PDGF receptor. The antibody is capable of inhibiting PDGF-induced mitogenesis of cells that display the human beta type PDGF receptor on the cell surface. The invention will be useful in diagnostic applications, and also for treating diseases involving PDGF-mediated proliferation, migration and chemotaxis of cells displaying the human type beta PDGF receptor.

Definitions

a) Proteins.

The terms "peptide", "polypeptide" or "protein" are used interchangeably herein. The term "substantial identity", when referring to polypeptides, indicates that the polypeptide or protein in question is at least about 30% identical to an entire naturally occurring protein or a portion thereof, usually at least about 70% identical, and preferably at least about 95% identical.

As used herein, the terms "isolated", "substantially pure" and "substantially homogenous" are used interchangeably and describe a protein that has been separated from components which naturally accompany it. Typically, a monomeric protein is substantially pure when at least about 60 to 75% of a sample exhibits a single polypeptide backbone. Minor variants or chemical modifications typically share the same polypeptide sequence. A substantially purified protein will typically comprise over about 85 to 90% of a protein sample, more usually about 95%, and preferably will be over about 99% pure. Protein purity or homogeneity may be indicated by a number of means well known in the art, such as polyacrylamide gel electrophoresis of a protein sample, followed by visualizing a single polypeptide band on a polyacrylamide gel upon staining. For certain purposes high resolution will be needed and HPLC or a similar means for purification utilized.

A polypeptide is substantially free of naturally-associated components when it is separated from the native

contaminants which accompany it in its natural state. Thus, a
polypeptide which is chemically synthesized or synthesized in a
cellular system different from the cell from which it naturally
originates will be substantially free from its naturally-
5   associated components.

       Proteins may be purified to substantial homogeneity by
standard techniques well known in the art, including selective
precipitation with such substances as ammonium sulfate, column
chromatography, immunopurification methods, and others. See,
10   for instance, R. Scopes, Protein Purification: Principles and
Practice, Springer-Verlag: New York (1982), which is
incorporated herein by reference.

b) Nucleic acids.

15   Nucleic acids, as used herein, may be DNA or RNA. When
referring to nucleic acids, the term "substantial identity"
indicates that the sequences of two nucleic acids, or
designated portions thereof, when optimally aligned and
compared, are identical, with appropriate nucleotide insertions
20   or deletions, in at least about 80% of the nucleotides, usually
at least about 90% to 95%, and more preferably at least about
98 to 99.5% of the nucleotides.

       Alternatively, substantial nucleic acid sequence
identity exists when a nucleic acid segment will hybridize
25   under selective hybridization conditions, to a complement of
another nucleic acid strand.

       "Substantially complementary" similarly means that one
nucleic acid is identical to, or hybridizes selectively to,
another nucleic acid. Typically, selective hybridization will
30   occur when there is at least about 55% identity over a stretch
of at least 14-25 nucleotides, preferably at least about 65%
identity, more preferably at least about 75%, and most
preferably at least about 90% identity. See, M. Kanehisa
Nucleic Acids Res. 12:203 (1984), which is incorporated herein
35   by reference.

       Stringent hybridization conditions will typically
include salt concentrations of less than about 1 M, more

usually less than about 500 mM and preferably less than about 200 mM. Temperature conditions will typically be greater than 22°C, more typically greater than about 30°C and preferably in excess of about 37°C. As other factors may dramatically affect the stringency of hybridization, including base composition and size of the complementary strands, presence of organic solvents and extent of base mismatching, the combination of parameters is more important than the absolute measure of any one alone.

"Isolated" or "substantially pure", when referring to nucleic acids, refer to those that have been purified away from other cellular components or other contaminants, e.g., other cellular nucleic acids or proteins, by standard techniques, including alkaline/SDS treatment, CsCl banding, column chromatography, and others well known in the art. See, F. Ausubel, et al., ed. Current Protocols in Molecular Biology, Greene Publishing and Wiley-Interscience, New York (1987), incorporated herein by reference.

A nucleic acid is "operably linked" when it is placed into a functional relationship with another nucleic acid sequence. For instance, a promoter or enhancer is operably linked to a coding sequence if it affects the transcription of the sequence. Generally, operably linked means that the nucleic acid sequences being linked are contiguous and, where necessary to join two protein coding regions, contiguous and in reading frame.

Techniques for nucleic acid manipulation, such as subcloning nucleic acid sequences encoding polypeptides into expression vectors, labelling probes, DNA hybridization, and so on are described generally, for example in Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual (2nd ed.), Vols. 1-3, Cold Spring Harbor Laboratory, or Ausubel et al., ed. (1987) op. cit., both of which are incorporated herein by reference.

"Expression vectors", "cloning vectors", or "vectors" are often plasmids or other nucleic acid molecules that are able to replicate in a chosen host cell. Expression vectors may replicate autonomously, or they may replicate by being

inserted into the genome of the host cell, by methods well
known in the art.   Vectors that replicate autonomously will
have an origin of replication or autonomous replicating
sequence (ARS) that is functional in the chosen host cell(s).
5   Often, it is desirable for a vector to be usable in more than
one host cell, e.g., in E. coli for cloning and construction,
and in a mammalian cell for expression.

          Mammalian cell lines are often used as host cells for
the expression of polypeptides derived from eukaryotes.
10   Propagation of mammalian cells in culture is per se well known.
See, Tissue Culture, Academic Press, Kruse and Patterson, ed.
(1973), incorporated herein by reference.   Host cell lines may
also include such organisms as bacteria (e.g., E. coli or B.
subtilis), yeast, filamentous fungi, plant cells, or insect
15   cells, among others.

          "Transformation" refers to the introduction of vectors
containing the nucleic acids of interest directly into host
cells by well known methods.   Transformation methods, which
vary depending on the type of host cell, include
20   electroporation; transfection employing calcium chloride,
rubidium chloride calcium phosphate, DEAE-dextran, or other
substances; microprojectile bombardment; lipofection; infection
(where the vector is an infectious agent); and other methods.
See generally, Sambrook et al., (1989) op. cit. and Ausubel et
25   al. (ed.), (1987) op. cit. Reference to cells into which the
nucleic acids described above have been introduced is meant to
also include the progeny of such cells.

     c) Antibodies.
30   As used herein, "immunoglobulin polypeptide" refers to
molecules which have specific immunoreactive activity.
Antibodies are typically tetramers of immunoglobulin
polypeptides. As used herein, the term "antibody" refers to a
protein consisting of one or more polypeptides substantially
35   encoded by immunoglobulin genes.   Immunoglobulin genes include
those coding for the light chains, which may be of the kappa or
lambda types, and those coding for the heavy chains, Heavy

chain types are alpha, gamma, delta, epsilon and mu. The carboxy terminal portions of immunoglobulin heavy and light chains are constant regions, while the amino terminal portions are encoded by the myriad immunoglobulin variable region genes. The variable regions of an immunoglobulin are the portions that provide antigen recognition specificity. In particular, the specificity resides in the complementarity determining regions (CDRs), also known as hypervariable regions, of the immunoglobulins. The immunoglobulins may exist in a variety of forms including, for example, Fv, Fab, and F(ab)$_2$, as well as in single chains (e.g., Huston, et al., Proc. Nat. Acad. Sci. U.S.A., 85:5879-5883 (1988) and Bird, et al., Science 242:423-426 (1988), which are incorporated herein by reference). (See, generally, Hood, et al., "Immunology", Benjamin, N.Y., 2nd ed. (1984), and Hunkapiller and Hood, Nature, 323:15-16 (1986), which are incorporated herein by reference). Single-chain antibodies, in which genes for a heavy chain and a light chain are combined into a single coding sequence, may also be used.

"Monoclonal antibodies" may be obtained by various techniques familiar to those skilled in the art. Briefly, spleen cells from an animal immunized with a desired antigen are immortalized, commonly by fusion with a myeloma cell (see, Kohler and Milstein, Eur. J. Immunol. 6:511-519 (1976)). Alternative methods of immortalization include transformation with Epstein Barr Virus, oncogenes, or retroviruses, or other methods well known in the art. Colonies arising from single immortalized cells are screened for production of antibodies of the desired specificity and affinity for the antigen, and yield of the monoclonal antibodies produced by such cells may be enhanced by various techniques, including injection into the peritoneal cavity of a vertebrate host.

Monospecific immunoglobulins may also be produced by recombinant techniques in prokaryotic or eukaryotic host cells.

"Chimeric" antibodies are encoded by immunoglobulin genes that have been genetically engineered so that the light and heavy chain genes are composed of immunoglobulin gene

segments belonging to different species. For example, the
variable (V) segments of the genes from a mouse monoclonal
antibody may be joined to human constant (C) segments. Such a
chimeric antibody is likely to be less antigenic to a human
than antibodies with mouse constant regions as well as mouse
variable regions.

As used herein, the term chimeric antibody also refers
to an antibody that includes an immunoglobulin that has a
human-like framework and in which any constant region present
has at least about 85-90%, and preferably about 95% polypeptide
sequence identity to a human immunoglobulin constant region, a
so-called "humanized" immunoglobulin (see, for example, PCT
Publication WO 90/07861, which is incorporated herein by
reference). Hence, all parts of such a "humanized"
immunoglobulin, except possibly the complementarity determining
regions (CDR's), are substantially identical to corresponding
parts of one or more native human immunoglobulin sequences.

The term "framework region", as used herein, refers to
those portions of immunoglobulin light and heavy chain variable
regions that are relatively conserved (i.e., other than the
CDR's) among different immunoglobulins in a single species, as
defined by Kabat, et al., (1987): Sequences of Proteins of
Immunologic Interest, 4th Ed., US Dept. Health and Human
Services, which is incorporated herein by reference). As used
herein, a "human-like framework region" is a framework region
that in each existing chain comprises at least about 70 or more
amino acid residues, typically 75 to 85 or more residues,
identical to those in a human immunoglobulin.

Human constant region DNA sequences can be isolated in
accordance with well known procedures from a variety of human
cells, but preferably from immortalized B-cells. The variable
regions or CDRs for producing the chimeric immunoglobulins of
the present invention will be similarly derived from monoclonal
antibodies capable of binding to the human type beta PDGF
receptor, and will be produced in any convenient mammalian
source, including, mice, rats, rabbits, or other vertebrate
capable of producing antibodies by well known methods.

Suitable source cells for the DNA sequences and host cells for immunoglobulin expression and secretion can be obtained from a number of sources, such as the American Type Culture Collection ("Catalogue of Cell Lines and Hybridomas,"

5   Fifth edition (1985) Rockville, Maryland, U.S.A., which is incorporated herein by reference).

In addition to the chimeric and "humanized" immunoglobulins specifically described herein, other substantially identical modified immunoglobulins can be readily

10 designed and manufactured utilizing various recombinant DNA techniques well known to those skilled in the art. In general, modifications of the genes may be readily accomplished by a variety of well-known techniques, such as site-directed mutagenesis (see, Gillman and Smith, Gene 8:81-97 (1979) and S.

15 Roberts et al., Nature 328:731-734 (1987), both of which are incorporated herein by reference).

Alternatively, polypeptide fragments comprising only a portion of the primary immunoglobulin structure may be produced. For example, it may be desirable to produce

20 immunoglobulin polypeptide fragments that possess one or more immunoglobulin activities in addition to, or other than, antigen recognition (e.g., complement fixation).

Immunoglobulin genes, in whole or in part, may also be combined with functional regions from other genes (e.g.,

25 enzymes), or with other molecules such as toxins or labels to produce fusion proteins (e.g., "immunotoxins") having novel properties. In these cases of gene fusion, the two components are present within the same polypeptide chain. Alternatively, the immunoglobulin or fragment thereof may be chemically bonded

30 to the toxin or label by any of a variety of well-known chemical procedures. For example, when the label or cytotoxic agent is a protein and the second component is an intact immunoglobulin, the linkage may be by way of heterobifunctional cross-linkers, e.g., SPDP, carbodiimide, glutaraldehyde, or the

35 like.

Suitable labels include, for example, radionuclides, enzymes, substrates, cofactors, inhibitors, fluorescers,

chemiluminescers, magnetic particles. See, for examples of
patents teaching the use of such labels, U.S. Patent Nos.
3,817,837; 3,850,752; 3,939,350; 3,996,345; 4,277,437;
4,275,149; and 4,366,241, all of which are incorporated by
5 reference.

Immunotoxins, including single chain molecules, may
also be produced by recombinant means. Production of various
immunotoxins is well-known with the art, and methods can be
found, for example in "Monoclonal Antibody-Toxin Conjugates:
10 Aiming the Magic Bullet," Thorpe et al, Monoclonal Antibodies
in Clinical Medicine, Academic Press, pp. 168-190 (1982); E.
Vitetta, Science (1987) 238:1098-1104; and G. Winter and C.
Milstein, Nature (1991) 349:293-299; all incorporated herein by
reference.

15 A variety of cytotoxic agents are suitable for use in
immunotoxins. Cytotoxic agents can include radionuclides,
such as Iodine-131, Yttrium-90, Rhenium-188, and Bismuth-212; a
number of chemotherapeutic drugs, such as vindesine,
methotrexate, adriamycin, and cisplatinum; and cytotoxic
20 proteins such as ribosomal inhibiting proteins like pokeweed
antiviral protein, Pseudomonas exotoxin A, ricin, diphtheria
toxin, ricin A chain, etc., or an agent active at the cell
surface, such as the phospholipase enzymes (e.g., phospholipase
C). (See, generally, "Chimeric Toxins," Olsnes and Pihl,
25 Pharmac. Ther., 15:355-381 (1981), and "Monoclonal Antibodies
for Cancer Detection and Therapy," eds. Baldwin and Byers, pp.
159-179, 224-266, Academic Press (1985), both of which are
incorporated herein by reference).

Description of the Invention

The immunoglobulin polypeptides of the present invention will find use in therapeutics as well as in diagnostics and other applications. Various techniques useful in these arts are discussed, for example, in Harlow and Lane, Antibodies: A Laboratory Manual, Cold Spring Harbor, New York (1988) (incorporated herein by reference for all purposes), including: immunization of animals to produce immunoglobulins; production of monoclonal antibodies; labeling immunoglobulins for use as probes; immunoaffinity purification; and immunoassays.

An example of an immunoglobulin polypeptide of the present invention is the monoclonal antibody 2A1E2, described below, which binds specifically to the type beta human PDGF receptor. Monoclonal antibody 2A1E2, which is of the IgG_1 isotype, was deposited with the American Type Culture Collection, 12301 Park Lawn Drive, Rockville, Maryland 20231 (ATCC no. HB10938), prior to the filing date of this application.

The anti-PDGF receptor immunoglobulin polypeptides of the present invention may be prepared by immunizing an animal with a purified or partially purified extracellular domain of human beta-type PDGF receptor. The animals immunized can be any one of a variety of species which are capable of immunologically recognizing epitopes characteristic of the human type beta PDGF receptor extracellular domain, such as murine, lagomorph, equine, etc.

Monoclonal antibodies of the invention may be prepared by immortalizing nucleic acid sequences which encode immunoglobulin polypeptides or portions thereof that bind specifically to antigenic determinants characteristic of the extracellular domain of the human type beta PDGF receptor. The immortalization process can be carried out by hybridoma fusion techniques, by viral transformation of antibody-producing lymphocytes, recombinant DNA techniques, or by techniques that combine cell fusion, viral transformation and/or recombinant DNA methodologies.

According to one aspect of the invention, cells
producing human anti-PDGF receptor monoclonal antibodies are
immortalized using, e.g., Epstein-Barr virus (EBV)
transformation techniques. For example, B lymphocytes derived
5   from peripheral blood, bone marrow, lymph nodes, tonsils, etc.
of patients, preferably those immunized with the PDGF receptor
or portions thereof, are immortalized using EBV according to
methods such as those described in U.S. Patent No. 4,464,465,
and Chan et al., J. Immunol. 136:106 (1986), which are
10   incorporated herein by reference.

Human anti-PDGF receptor monoclonal antibodies can also
be prepared by a variety of other ways, e.g., using a
combination of EBV or other viral transformation and hybridoma
fusion techniques. For instance, the hybridomas can be created
15   by fusing stimulated B cells, obtained from a individual
immunized with the PDGF receptor or a portion thereof, with a
mouse/human heterohybrid fusion partner, a variety of which
have been described. See, e.g., U.S. Pat. No. 4,624,921 and
James and Bell, J. Immunol. Meths. 100:5-40 (1987), which are
20   incorporated herein by reference. A mouse/human fusion partner
can be constructed by fusing human lymphocytes stimulated or
transformed by EBV with readily available mouse myeloma lines
such as NS-1 or P3NS-1, in the presence of, e.g., polyethylene
glycol. The hybrid should be suitably drug-marked, which can
25   be accomplished by cultivating the hybrid in increasing
concentrations of the desired drug, such as 6-thioguanine,
ouabain, or neomycin.

The hybridomas or lymphoblastoid cells which secrete
antibody of interest can be identified by screening culture
30   supernatants for antibody that binds to the type beta PDGF
receptor. More preferably, a screening assay may be employed
to detect those antibodies which inhibit, for example,
PDGF-mediated mitogenesis. Cells which possess the desired
activity are cloned and subcloned in accordance with
35   conventional techniques and monitored until stable,
immortalized lines producing the anti-PDGF receptor monoclonal
antibody of interest are identified. By monoclonal antibody is

20

meant an antibody produced by a clonal, immortalized cell line
separate from cells producing antibodies with a different
antigen binding specificity. Thus, such monoclonal antibodies
are produced isolated from other monoclonal antibodies and,
5   accordingly, in substantially pure form (relative to other
antibodies) and at a concentration generally greater than
normally occurring in sera from the animal species which serves
as a B cell source.

Alternatively, one can isolate DNA sequences which
10   encode a human anti-PDGF receptor immunoglobulin polypeptide or
portions thereof that specifically bind to the extracellular
domain of the PDGF receptor by screening a DNA library from
human B cells according to a general protocol as outlined by
Huse et al., Science 246:1275-1281 (1989), incorporated herein
15   by reference, and then cloning and amplifying the sequences
which encode the anti-PDGF receptor antibodies (or binding
fragment) of the desired specificity.

The immunoglobulins may then be produced by introducing
an expression vector containing the appropriate immunoglobulin
20   gene, or portion thereof, into an appropriate host cell. The
host cell line is then maintained under conditions suitable for
high level expression of the immunoglobulin nucleotide
sequences, and, as desired, the collection and purification of
the light chains, heavy chains, light/heavy chain dimers or
25   intact antibodies, binding fragments or other immunoglobulin
forms may follow.

Suitable host cells include microorganisms, but
mammalian or insect tissue cell culture may be preferable for
producing the monoclonal antibody of the present invention
30   (see, E. Winnacker, "From Genes to Clones," VCH Publishers,
N.Y., N.Y. (1987), which is incorporated herein by reference).
A number of suitable host cell lines capable of secreting
intact immunoglobulins have been developed in the art, and
include the Chinese hamster ovary (CHO) cell line, but
35   preferably transformed B-cells or hybridomas will be used.

Once expressed, the whole antibodies, their dimers,
individual light and heavy chains, or other immunoglobulin

forms of the present invention can be purified according to standard procedures of the art, including ammonium sulfate precipitation, affinity columns, column chromatography, gel electrophoresis and the like (see, generally, R. Scopes, Protein Purification, Springer-Verlag, N.Y. (1982), incorporated herein by reference). Substantially pure immunoglobulins of at least about 90 to 95% homogeneity are preferred, and those of 98 to 99% or greater homogeneity most preferred, for pharmaceutical uses. Once purified, partially or to homogeneity as desired, the polypeptides may then be used therapeutically (including extracorporeally) or in developing and performing assay procedures, immunofluorescent stainings, and the like. (See, generally, Immunological Methods, Vols. I and II, Lefkovits and Pernis, eds., Academic Press, New York, N.Y. (1979 and 1981), which are incorporated herein by reference).

The immunoglobulin polypeptides produced according to the present invention may be of the IgG, IgM, IgA or IgD isotype, and may further be any of the appropriate subclasses thereof, such as, e.g., IgG_1, IgG_2, IgG_3, or IgG_4. Using recombinant DNA techniques, "class-switching" of the isolated immunoglobulin polypeptides may be readily accomplished. In this method genes encoding the constant regions which determine the isotype of the immunoglobulin molecule of interest are replaced by genes encoding a desired isotype or subclass, as generally described in European patent publication EP 314,161, incorporated herein by reference. Class-switched immunoglobulins may also be isolated by selecting cells which have undergone spontaneous switching using selection methods known in the art.

The administration to humans of immunoglobulin polypeptides which are substantially non-human may elicit anti-antibody responses. Thus, it may be desirable to prepare anti-PDGF receptor immunoglobulin polypeptides of the present invention which are substantially human. By "substantially human" is meant an antibody or binding fragment thereof comprised of amino acid sequences which are at least about 50%

human in origin, at least about 70 to 80% more preferred, and
about 95-99% or more human most preferred, particularly for
repeated administrations over a prolonged period as may be
necessary to treat established PDGF-mediated cell proliferation
5   disorders.   As used herein, human antibody is meant to include
antibodies of entirely human origin as well as those which are
substantially human, unless the context indicates otherwise.

As the generation of human anti-PDGF receptor
monoclonal antibodies may be difficult with conventional
10   immortalization techniques, it may be desirable to first make
non-human antibodies and then transfer via recombinant DNA
techniques the antigen binding regions of the non-human
antibodies, e.g., the Fab, complementarity determining regions
(CDRs) or hypervariable regions, to human constant regions (Fc)
15   or framework regions as appropriate to produce substantially
human molecules. Such methods are generally known in the art
and are described in, for example, U.S. 4,816,397, PCT
publication WO 90/07861, and EP publications 173494 and 239400,
wherein each is incorporated herein by reference.

20   The resulting chimeric antibodies or chimeric
immunoglobulin polypeptides that specifically bind to the human
type beta PDGF receptor and thus inhibit binding of PDGF to the
receptor are also within the scope of the present invention.   A
typical therapeutic chimeric antibody would be a hybrid protein
25   consisting of the variable (V) or antigen-binding domain from a
mouse immunoglobulin specific for a human PDGF type beta
receptor antigenic determinant, and the constant (C) or
effector domain from a human immunoglobulin, although domains
from other mammalian species may be used for both variable and
30   constant domains. As used herein, the term "chimeric antibody"
also refers to antibodies coded for by immunoglobulin genes in
which only the complementarity determining regions (CDR's) are
transferred from the immunoglobulin that specifically
recognizes the antigenic determinants, the remainder of the
35   immunoglobulin gene being derived from a human (or other
mammalian, as desired) immunoglobulin gene. This type of

chimeric antibody is referred to as a "humanized" (in the case
of a human immunoglobulin gene being used) antibody.

The hypervariable regions of the variable domains of
the anti-PDGF receptor immunoglobulin polypeptides comprise a
5   related aspect of the invention. The hypervariable regions, or
CDRs, in conjunction with the framework regions (those portions
of immunoglobulin light and heavy chain variable regions that
are relatively conserved among different immunoglobulins in a
single species), enable the anti-PDGF receptor immunoglobulin
10   polypeptides to recognize and thus bind to the human type beta
PDGF receptor. The hypervariable regions can be cloned and
sequenced. Once identified, these regions that confer specific
recognition of the PDGF receptor can then be cloned into a
vector for expression in a host as part of another
15   immunoglobulin molecule or as a fusion protein, e.g., a carrier
molecule which functions to enhance immunogenicity of the
cloned idiotope.

The anti-PDGF receptor immunoglobulin polypeptides of
the invention will generally be used intact, or as immunogenic
20   fragments, such as F_v, Fab, or $F(ab')_2$ fragments. The fragments
may be obtained from antibodies by conventional techniques,
such as by proteolytic digestion of the antibody using, e.g.,
pepsin or papain, or by recombinant DNA techniques in which a
gene or portion thereof encoding the desired fragment is cloned
25   or synthesized, and expressed in a variety of hosts.

Those skilled in the art will realize that "anti-
idiotypic" antibodies can be produced by using a specific
immunoglobulin as an immunogen in accordance with standard
techniques. For example, infection or immunization with a PDGF
30   receptor polypeptide, or fragment thereof, induces a
neutralizing immunoglobulin, which has on its Fab variable
region combining site an image of the PDGF receptor polypeptide
that is unique to that particular immunoglobulin, i.e., an
idiotype. Immunization with such an anti-PDGF-R immunoglobulin
35   induces an anti-idiotype antibody, which has a conformation at
its combining site that mimics the structure of the original
PDGF-R antigen. These anti-idiotype antibodies may therefore

be used instead of the PDGF-R antigen to treat PDGF-mediated diseases (see, for example, Nisonoff (1991) J. Immunol. 147:2429-2438, which is incorporated herein by reference).

5   The anti-PDGF receptor immunoglobulin polypeptides of the invention find utility in therapeutic and diagnostic methods and compositions. For therapeutic uses, anti-PDGF receptor immunoglobulin polypeptides are used as a soluble ligand for human type beta PDGF receptor, masking the receptor or otherwise inhibiting PDGF molecules from binding to the

10   receptor, and thereby inhibiting the undesired cell migration and proliferation.

    For pharmaceutical compositions, the anti-PDGF receptor immunoglobulin polypeptides of the invention as described herein are administered to an individual having a PDGF-mediated

15   cellular proliferation disorder. In therapeutic applications, compositions are administered to a patient in an amount sufficient to effectively block cell receptors, and thereby cure or at least partially arrest the cellular proliferation and its symptoms and/or complications. An amount adequate to

20   accomplish this is defined as "therapeutically effective dose." Amounts effective for this use will depend on, e.g., the nature of the anti-PDGF receptor immunoglobulin polypeptide composition, the manner of administration, the stage and severity of the disease being treated, the weight and general

25   state of health of the patient, and the judgment of the prescribing physician, but will generally range from about 0.01 mg/kg to about 100.0 mg/kg of antibody per day, with dosages of from about 0.1 mg/kg to about 10.0 mg/kg of antibody per day being more commonly used. It must be kept in mind that the

30   anti-PDGF receptor immunoglobulin polypeptide and peptide compositions derived therefrom may be employed in serious disease states, that is, life-threatening or potentially life threatening situations. In such cases, it is possible and may be felt desirable by the treating physician to administer

35   substantial excesses of these compositions. Thus, human anti-PDGF receptor monoclonal antibodies or substantially human

anti-PDGF receptor monoclonal antibodies of the invention are most preferred under these circumstances.

Single or multiple administrations of the compositions can be carried out with dose levels and pattern being selected by the treating physician. In any event, the pharmaceutical formulations should provide a quantity of anti-PDGF receptor immunoglobulin polypeptide of the invention sufficient to effectively treat the patient. Administration should begin at the first indication of undesirable cellular proliferation or shortly after diagnosis, and continue until symptoms are substantially abated and for a period thereafter. In well established cases of disease, loading doses followed by maintenance doses will be required.

The pharmaceutical compositions for therapeutic treatment are intended for parenteral, topical, oral or local administration. Preferably, the pharmaceutical compositions are administered parenterally, e.g., intravenously, subcutaneously, intradermally, or intramuscularly. Thus, the invention provides compositions for parenteral administration which comprise a solution of the anti-PDGF receptor immunoglobulin polypeptide dissolved or suspended in an acceptable carrier, preferably an aqueous carrier. A variety of aqueous carriers may be used, e.g., water, buffered water, 0.4% saline, 0.3% glycine, hyaluronic acid and the like. These compositions may be sterilized by conventional, well known sterilization techniques, or may be sterile filtered. The resulting aqueous solutions may be packaged for use as is, or lyophilized, the lyophilized preparation being combined with a sterile solution prior to administration. The compositions may contain pharmaceutically acceptable auxiliary substances as required to approximate physiological conditions, such as pH, adjusting and buffering agents, tonicity adjusting agents, wetting agents and the like, for example, sodium acetate, sodium lactate, sodium chloride, potassium chloride, calcium chloride, sorbitan monolaurate, triethanolamine oleate, etc.

The concentration of anti-PDGF receptor immunoglobulin polypeptides of the invention in the pharmaceutical

formulations can vary widely, i.e., from less than about 1%, usually at or at least about 10-15% to as much as 50% or more by weight, and will be selected primarily by fluid volumes, viscosities, etc., in accordance with the particular mode of administration selected.

Thus, a typical pharmaceutical composition for intravenous infusion could be made up to contain 250 ml of sterile Ringer's solution, and 100 mg of anti-PDGF receptor immunoglobulin polypeptide. Actual methods for preparing parenterally administrable compounds will be known or apparent to those skilled in the art and are described in more detail in for example, Remington's Pharmaceutical Science, 17th ed., Mack Publishing Company, Easton, PA (1985), which is incorporated herein by reference.

The anti-PDGF receptor immunoglobulin polypeptides and fragments thereof can also be administered via liposomes. The anti-PDGF receptor immunoglobulin polypeptides can serve to target the liposomes to particular tissues or cells displaying the human type beta PDGF receptor. Liposomes include emulsions, foams, micelles, insoluble monolayers, liquid crystals, phospholipid dispersions, lamellar layers and the like. In these preparations the immunoglobulin polypeptide or fragment to be delivered is incorporated as part of the liposome, alone or in conjunction with a molecule which is, for example, toxic to the target cells. A liposome suspension containing an immunoglobulin polypeptide can be administered intravenously, locally, topically, etc. in a dose which varies according to, inter alia, the manner of administration, the peptide being delivered, and the stage of disease being treated.

For solid compositions of the anti-PDGF receptor immunoglobulin polypeptides of the invention, conventional nontoxic solid carriers may be used which include, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talcum, cellulose, glucose, sucrose, magnesium carbonate, and the like. For oral administration, a pharmaceutically acceptable nontoxic

composition is formed by incorporating any of the normally
employed excipients, such as those carriers previously listed,
and generally 10-95% of active ingredient, that is, one or more
anti-PDGF receptor immunoglobulin polypeptides, and more

5   preferably at a concentration of 25%-75%.

For diagnostic purposes, the anti-PDGF receptor
immunoglobulin polypeptides may either be labeled or unlabeled.
A label is a substance that provides a detectable signal by any
of a variety of techniques well known and reported in the art.

10   The immunoglobulin polypeptides of the invention themselves may
be directly labeled. Alternatively, unlabeled antibodies
included in the invention may be used in combination with other
antibodies (second antibodies) that are labelled and that
recognize the anti-PDGF receptor immunoglobulin polypeptides of

15   the present invention. For example, labelled antibodies
specific for the constant regions of the anti-PDGF receptor
immunoglobulin polypeptides may be used to detect the
immunoglobulin polypeptide bound to a sample.

A wide variety of labels may be employed, such as

20   radionuclides, fluors, enzymes, enzyme substrates, enzyme
cofactors, enzyme inhibitors, ligands (particularly haptens),
etc. Numerous types of immunoassays are available and are well
known to those skilled in the art.

The anti-PDGF receptor immunoglobulin polypeptides, and

25   fragments thereof, of the present invention may be used in
various immunoassays for detecting PDGF receptor in
physiological specimens. Such immunoassay methods may include
liquid phase immunoassays and Western blot analysis,
competitive and noncompetitive protein binding assays,

30   enzyme-linked immunosorbant assays (ELISA), an others commonly
used and widely described in scientific and patent literature,
and many employed commercially.

Such immunoglobulins and peptides may likewise be
employed in immunohistochemical staining techniques by methods

35   well known in the art.

The following example is offered by way of illustration
and not limitation.

EXAMPLE

Materials

PDGF BB was purchased from Amgen. Anti-phosphotyrosine
monoclonal antibody (MAb) PY20 was purchased from ICI. DMEM,
RPMI 1640, F12, calf serum, penicillin-streptomycin solution,
G418-Neomycin, 200 mM glutamine, 1M HEPES, sodium pyruvate (11
mg/ml), and phosphate buffered saline (PBS) were from GIBCO.
Fetal calf serum (FCS) and the monoclonal antibody subtyping
kit was from Hyclone. Tris, sodium phosphate, sodium borate,
acetic acid, sodium pyrophosphate, sodium fluoride,
dithiothreitol (DTT), ethylenediamine tetraacetic acid (EDTA),
EGTA, sodium dodecyl sulphate (SDS), sodium orthovanadate,
sodium chloride (NaCl), citric acid, phenyl methyl sulphonyl
fluoride (PMSF), bovine serum albumin (BSA), Triton X100, Tween
20, 2,2' Azino-bis(3-ethylbenzthiazoline)-6-sulphonic acid
(ABTS), and hydrogen peroxide were from Sigma. Goat anti-mouse
peroxidase and hypoxanthine-thiamine (HT) were from Boehringer
Mannheim. Gelatin, unstained protein molecular weight markers
and nitrocellulose were from BioRad. Prestained high molecular
weight protein markers were from BRL. Protein A sepharose
CL4B, Protein G sepharose CL4B, Immunopure™ binding buffer,
F(ab!)$_2$ and Fab preparation kits were from Pierce. Prepacked
PD10 columns were from Pharmacia. ^{125}I-Protein A and
^{14}C-molecular weight markers were from Amersham.
^{125}I-diiodo-Bolton-Hunter reagent was from New England Nuclear.
Methanol was from Burdick-Jackson. Tissue culture supplies
were from Costar. AG01523B cells were obtained from ATCC. HR5
cells were kindly provided by J.A. Escobedo (UCSF). Primary
baboon brachial artery smooth muscle cells were generously
provided by J. Anderson and S. Hanson (Emory Univ.).

Methods

Cell culture. NIH 3T3 cells were routinely maintained
in DMEM containing 10% fetal calf serum, 1X penicillin-
streptomycin, 2 mM glutamine, and sodium pyruvate (0.11 mg/ml).
CHO cells expressing the extracellular domain (pΔ1-5) or the

full-length PDGF beta receptor (HR5) were cultured in RPMI
containing 10% FCS, 1X penicillin-streptomycin, 2 mM glutamine,
sodium pyruvate (0.11 mg/ml) and G418 (200 μg/ml). Human
foreskin fibroblast cells (AG01523B) were cultured in DMEM

5   containing 10% FCS, 1X penicillin-streptomycin, 2 mM glutamine,
and sodium pyruvate (0.11 mg/ml). Monoclonal hybridoma cells
were maintained in 50:50 DME:RPMI containing 20% FCS, 1X
penicillin-streptomycin, 2 mM glutamine, sodium pyruvate (0.1
mg/ml), 1X HT, and 10% macrophage-conditioned medium.

10   Construction of Truncated Human PDGF beta
receptor-expressing cell lines. Truncation of the human PDGF
beta receptor cDNA was performed by oligonucleotide-directed
deletion mutagenesis. Oligonucleotide-directed in vitro
mutagenesis was performed according to a modified method of

15   Kunkel et al. (1987) Meth. Enzymol. 154: 367-382, which is
incorporated herein by reference). Initially a 3.9 kb
EcoRI-HindIII cDNA fragment of the entire coding region of the
human PDGF beta receptor (residues -32 to 499) was subcloned
into the EcoRI and HindIII sites of ml3mpl8 generating vector

20   mpl8PR (Maniatis, T. et al. (1982) Molecular Cloning: A
Laboratory Manual, Cold Spring Harbor Laboratory, Cold Spring
Harbor, NY, which is incorporated herein by reference).

              Oligonucleotides were designed to delete the portions
of the human PDGF beta receptor cDNA that code for amino acids

25   499-1074 (PRΔ1; GTG TGA GGA ACG GGA AAT TCA TCG AAG GAC ATC CCC
CGAC), or amino acids 384-1074 (PRΔ2; GGA AGG TCG ATG TCT AGT
TAA TCG AAG GAC ATC CCC CGAC) (Fig 1.). A stop codon was
introduced after residue 499 (PRΔ1) or residue 384 (PRΔ2).
Verification of subcloning was performed by restriction enzyme

30   digestion analysis and dideoxy chain termination sequencing
(Sanger, F. et al. (1977) Proc. Natl. Acad. Sci. USA, 74:
5463-5467, which is incorporated herein by reference).

              The modified PDGF beta receptor polypeptides were
subcloned into the EcoRI and HindIII sites of the expression

35   vector PBJ1 (Lin, A. et al. (1990) Science 249: 677-679, which
is incorporated herein by reference) and cotransfected with
vector pSV2Neo (Southern, P.J. and Berg, P. (1982) J. Mol.

Appl. Gen. 1: 327-341, which is incorporated herein by
reference) at a ratio of 1:10 into CHO-K1 cells by the method
of lipofectin reagent uptake (Felgner, P.L. et al. (1987) Proc.
Natl. Acad. Sci. USA 84: 7413-7417, which is incorporated

5   herein by reference). Transfected cells were selected for
G418-neomycin resistance, and individual clones were isolated
and screened at equal cell density for high level expression of
extracellular PDGF beta receptor in serum-free medium.
Expression of the modified extracellular PDGF beta receptor

10   proteins was determined by Western blot analysis using a rabbit
polyclonal serum (Ab 1-3-5, see Fig 1) raised against a
synthetic peptide based on human PDGF receptor residues 51-68
(SVLTLTNLTGLDTGEYFC SEQ ID NO:3). Recombinant clones pΔ1-5
(expressing full-length extracellular PDGF receptor) and pΔ2-7

15   (expressing domains 1-4 of the extracellular PDGF receptor)
were used for subsequent protein production.

        Preparation of MAbs against human PDGF beta receptor.
Antibodies were developed as described by Harlow and Lane
(1988, In Antibodies: A Laboratory Manual, Cold Spring Harbor

20   Laboratory, Cold Spring Harbor, NY, which is incorporated
herein by reference). Mice were immunised with partially
purified extracellular domain of PDGF beta receptor (pΔ1-5)
using 50-100 µg/immunisation). The titre of antibody in the
immunised mice was determined using an enzyme-linked

25   immunosorbent assay (ELISA), as follows. 96-well Immunolon II
microtitre plates were coated overnight at 4°C with partially
purified (10-15%) extracellular domain of PDGF beta receptor
(200-300 ng/well). The remaining manipulations were conducted
at room temperature. The wells were blocked with 0.05 M Tris,

30   pH 7 containing 100 mM NaCl and 0.5% gelatin for 1 hour.
Plates were incubated for 2 hours with various dilutions of
mouse sera, washed 5X with wash buffer (0.05 M Tris, pH7, 100
mM NaCl and 0.3% gelatin) and incubated with goat anti-mouse
peroxidase (1:1000 in wash buffer) for 1 hour. Plates were

35   washed as previously described and developed with
2,2'-Azino-bis(3ethylbenzthiazoline)6-sulphonic acid (ABTS, 1
mg/ml) in 0.1 M citric acid, 0.1 M dibasic sodium phosphate, pH

4, containing hydrogen peroxide (0.003% final concentration).
The absorbence at 650 nm was determined, and the values were
compared to the values obtained with protein purified to a
similar extent from conditioned media from CHO cells
5   transfected with the pBJ vector alone.

Mice showing high reactivity were sacrificed and the
spleens were isolated. Splenocytes were removed and fused with
myeloma cells P3X as described (Harlow and Lane, op. cit.).
Hybridomas were screened using the same ELISA, and positive
10   hybridomas were cloned and rescreened. Positive monoclonal
cells were cultured and ascites was prepared in Balb/c mice as
described (Harlow and Lane, op. cit.). Tissue culture media
was used to sub-type the MAbs, using the subtyping kit from
HyClone as instructed by the manufacturer.

15   Purification of Antibodies. Antibodies were purified
on Protein A sepharose CL4B as follows. Ascites fluid was
diluted 1:5 in Immunopure™ binding buffer (Pierce) and
chromatographed over a Protein A sepharose CL4B column
equilibrated in the same buffer. The flow through was
20   collected and the column was washed with Immunopure binding
buffer (10 column volumes). The bound IgGs were eluted with
0.1 M glycine, pH 2.8, and collected in tubes containing 2 M
Tris, pH 11 (40 μl/ml) as neutralising agent. The peak protein
fractions were detected by measuring the absorbence at 280 nm,
25   pooled and dialysed in PBS (2 changes of 4 L each).

Preparation of MAb 2A1E2 F(ab')$_2$ and Fab Proteolytic
Fragments. F(ab')$_2$ fragments of MAb 2A1E2 were prepared from
intact MAb using the Immunopure F(ab')$_2$ preparation kit
(Pierce) according to the manufacturer's instructions.
30. Monoclonal antibody 2A1E2 was incubated with immobilised pepsin
for 4 hours at 37°C at pH 4.2, and the uncleaved IgG and Fc
fragments were separated from the F(ab')$_2$ fragments using
Protein A sepharose CL4B. Fab fragments were similarly
prepared using the Pierce Immunopure Fab preparation kit. The
35   IgG was incubated with immobilised papain for 5 hours at 37°C
at pH 7, and undigested IgG and Fc fragments were removed using
Protein A. The samples were analysed by SDS-PAGE after

enzymatic digestion, and the PDGF beta receptor ELISA was used
to determine loss, if any, of antigen recognition.

Immunoprecipitation Assay. Immunoprecipitations were
done by a modification of the procedure of Kessler, S.W. (1981,
5 Meth. Enzymol. 73: 442-471, which is incorporated herein by
reference). When purified pΔ1-5 or pΔ2-7 were used, the
protein was incubated with MAb for either 2 hours at room temp
or 12 hours at 4°C in immunoprecipitation (IP) buffer (40 mM
Tris, pH 8, 100 mM NaCl, 10 mM EDTA, 1 mM EGTA and 1% Triton
10 X100). If full-length receptor was immunoprecipitated, then
cells expressing the PDGF beta receptor were solubilised in IP
buffer containing 1 μM sodium orthovanadate and 1 mM PMSF, and
incubated with the MAb for 8-12 hours at 4°C. Then the samples
were incubated with a 50% slurry of a 1:1 mixture of Protein
15 A-Sepharose CL4B and Protein G-sepharose CL4B (50-100
μl/sample). After 1-2 hours at 4°C, the resin was washed by 3
cycles of centrifugation and resuspension in IP buffer, and
finally the resin was boiled in Laemmli sample solubilising
buffer (50-100 μl/sample) (1970, Nature 227: 680-685, which is
20 incorporated herein by reference). The samples were subjected
to SDS-PAGE on a 7% or 10% Laemmli gel, and then transferred to
nitrocellulose. The western blot was blocked in blocking
buffer (0.05 M Tris, pH 8 containing 0.5% NaCl and 4% BSA), and
incubated with the primary antibody for 12 hours at 4°C. The
25 nitrocellulose was washed with blocking buffer and incubated
with ^{125}I-Protein A (0.4 mCi/ml) for 1-2 hours at room temp and
exposed to X-ray film.

Radioiodination of PDGF BB. PDGF BB was iodinated by a
modification of the Bolton-Hunter procedure described by Duan
30 et al. (1991, J. Biol. Chem. 266: 413-418, which is
incorporated herein by reference). Briefly, ^{125}I-diiodo
Bolton-Hunter reagent (1 mCi) was dried under nitrogen. Then,
PDGF BB (2.5 μg) was added to the ^{125}I-diiodo Bolton-Hunter
reagent in 10 μl of 0.1 M sodium borate (pH 8.5), for 15 min at
35 4°C. The reaction mixture was quenched with 500 μl of 0.1 M
sodium borate, 0.2 M glycine, pH 8.5, for 10 min at 4°C. This
material was subjected to gel filtration chromatography on a

PD10 column previously equilibrated with 0.3 M acetic acid
containing 1 mg/ml BSA. Peak radiolabelled protein fractions
were detected using a gamma counter. Typically the specific
activity of iodinated PDGF BB was 50000 counts/ng.

5   Binding of ^{125}I-PDGF BB to intact HR5 cells. HR5 cells
were harvested with PBS containing 2 mM EDTA for 20 min at
37°C. Washed HR5 cells (1×10^6 cells/100 μl) were incubated in
triplicate in suspension with various concentrations of MAb (or
F(ab')$_2$ or Fab fragments) in PBS containing 0.5% BSA for 30 min
10   at room temp. HR5 cells were incubated with ^{125}I-PDGF BB
(approx. 1 ng/tube) in the absence (total binding) or presence
(non-specific binding) of 100-fold excess unlabelled PDGF BB
and carrier protein (platelet poor plasma, 50 μl) for 45 min at
room temp. The final volume of the incubation was 500 μl. The
15   incubation mixture (400 μl) was layered on Ficoll-paque (700
μl) and centrifuged. The supernatant was removed and the
radioactivity in the cell pellet was determined.

           Phosphorylation Assay. HR5 cells were grown to
confluence in 6-well dishes and primary cells were cultured in
20   100 mm dishes. Cells were washed twice with cold serum-free
DMEM, and incubated on ice for 10 min. Cells were preincubated
in duplicate with MAb 2A1E2 for 30-45 min on ice on a rotary
shaker, and then ligand PDGF BB was added to the wells and the
incubation was continued for 1.5-2 hours. Cells were washed
25   twice with cold PBS and solubilised in either Lysis Buffer (100
mM Tris, pH8, 30 mM sodium pyrophosphate, 50 mM sodium
fluoride, 5 mM EDTA, 5 mM EGTA, 1% SDS, 100 mM DTT), or in IP
buffer, both containing 1 mM PMSF and 1 μM sodium
orthovanadate. Samples were then processed further prior to
30   electrophoresis.

           Mitogenesis in human foreskin fibroblast AG01523B cells
and baboon smooth muscle cells. Human foreskin fibroblast
AG01523B cells and baboon smooth muscle cells were gown to
confluence in 96-well dishes. Baboon smooth muscle cells were
35   quiesced by incubating overnight with DMEM containing 0.5% calf
serum. Cells were then incubated in triplicate with various
concentrations of MAb 2A1E2 in the presence of PDGF BB for 18

hours at 37°C, followed by 5 hours at 37°C with 2 μCi/well of ^{3}H-thymidine. Control baboon primary smooth muscle cells were incubated in parallel with a non-specific MAb and control AG01523B cells were incubated with a non-inhibitory anti-PDGF beta receptor Mab (4C5C8). Wells were then washed with ice-cold 5% TCA (2 x 250 μl), and solubilized with 0.25 N NaOH (2 x 100 μl). The solubilized samples were transferred to scintillation vials and radioactivity was determined.

Dimerisation Assay. Confluent HR5 cells were cultured as described above in 100 mm dishes. Cells were washed twice in cold PBS, and incubated with various concentrations of MAb 2A1E2 in PBS containing BSA (1.5 mg/ml) and 25 mM Hepes for 1 hour at 4°C. PDGF BB was added to the cells and the incubation was continued for 2 hours at 4°C. Cells were washed twice in cold PBS, and incubated for 30 min at 4°C with cross-linker BS^3 (0.75 mg/plate) in PBS containing 25 mM Hepes. The reaction was terminated by dilution in quench buffer (0.025 M Tris, pH 7.4, containing 150 mM NaCl; 10 ml/plate). Cells were extracted for 20 min at 4°C in IP buffer containing 1mM PMSF and 100 μM sodium orthovanadate (0.5 ml/plate). Cell lysates were immunoprecipitated overnight at 4°C using polyclonal anti-human beta receptor Ab (AB88, 1:500 dilution). Then, Protein A CL4B (60 μl of a 50% slurry) was added to each sample. After 1 hour at 4°C, beads were washed serially with PBS containing 0.5% NP40, 0.5 M lithium chloride containing 0.5% NP40, 0.5 M lithium chloride, and finally with water. Samples were solubilised with Laemmli sample solubilising buffer, and subjected to SDS-polyacrylamide gel electrophoresis on a 3%-8% gradient gel, followed by Western transfer to nitrocellulose. Western blots were either incubated with antiphosphotyrosine MAb (1:1000), or with Ab88 (1:500 dilution) overnight at 4°C, followed by ^{125}I-Protein A (0.15 μCi/ml) for 2 hours at room temp. Western blots were then exposed to X-ray film.

Results

Properties of MAb 2A1E2. MAb 2A1E2 is an IgG$_1$ monoclonal antibody. Western analysis shows that MAb 2A1E2

recognises non-reduced human PDGF beta receptor (Fig 2, Panel
A, Lane 4) but does not recognise reduced protein (Fig 2, Panel
A, Lane 1). MAb 2A1E2 immunoprecipitates full-length
extracellular receptor (pΔ1-5; residues 1-499) from solution
5   (Fig 2, Panel C, Lane 3). However, when purified pΔ2-7
(without domain 5; residues 1-384) is the antigen, there is no
reactivity (Fig 2, Panel B, Lane 2). This data indicates that
the epitope recognised by MAb 2A1E2 lies within the fifth Ig-
like domain, that is, between residues 385-499 of the human
10   PDGF beta receptor.

           Dose-dependent inhibition of ^{125}I-PDGF BB binding to HR5
cells by MAb 2A1E2. When HR5 cells (CHO-K cells which express
the full length human PDGF beta receptor) are incubated first
with MAb 2A1E2 followed by ^{125}I-PDGF BB, significant (48.1%)
15   inhibition is observed at a concentration as low as 0.1 nM MAb,
compared to cells not treated with MAb 2A1E2. When 1 nM or
greater concentrations of MAb 2A1E2 are used, there is 100%
inhibition of ligand binding to the full-length PDGF beta
receptor on the cells (Fig 3, Panel A). When 200 nM of a
20   different, non-inhibitory MAb (4C5C8) to PDGF beta receptor is
used in the preincubation, the amount of inhibition is only
36.1%. This is comparable to the effect of 200 nM of a
non-relevant MAb (anti-IIb/IIIa) (19.18% inhibition). The
amount of ^{125}I-PDGF BB binding in the presence of 1 nM MAb 2A1E2
25   is equivalent to the amount of ligand binding seen in the
presence of 1500-fold excess of unlabelled PDGF BB (Fig. 3,
Panel A), or the amount of binding of ligand to non-transfected
CHO cells that do not express a human PDGF receptor (data not
shown).

30   To determine if the inhibition seen with MAb 2A1E2 was
due to steric hindrance, we prepared F(ab')$_2$ and Fab fragments
of the MAb. These proteolytic fragments of the antibody still
recognised the PDGF beta receptor in ELISA (data not shown),
though their activity was diminished slightly. When these were
35   used in the radiolabelled ligand binding assay, we found that
the antibody fragments still inhibited binding of ^{125}I-PDGF BB
to the full-length PDGF beta receptor on HR5 cells in a

concentration-dependent manner (Fig 3, Panel B). However, complete inhibition was seen with 10 nM MAb 2A1E2 F(ab')$_2$ or Fab fragments, whereas 1 nM intact antibody completely inhibited binding. Binding of ligand in the presence of 1 nM

5   F(ab')$_2$ fragments was inhibited by 64.5%, and binding in the presence of 1 nM Fab fragments was inhibited by 50%.

Inhibition of Phosphorylation by MAb 2A1E2. As shown in Fig 4, MAb 2A1E2 specifically inhibited PDGF induced phosphorylation in HR5 cells in a concentration-dependent

10   manner, with approximately 50% inhibition occurring at a concentration of 1.3 nM (Lane 4) and 100% inhibition occurring at 13.3 nM MAb 2A1E2 (Lane 5). Control nonrelevant MAb (anti-IIb/IIIa) had no effect (Lane 3) and MAb 4C5C8, which was also developed against the human PDGF beta receptor but

15   recognises a different epitope, had no effect on ligand-induced phosphorylation (Lane 8).

Effect of MAb 2A1E2 on PDGF BB Induced Dimerisation of the Human PDGF beta Receptor. Treatment of HR5 cells with PDGF BB results in ligand-mediated phosphorylation (Fig 5, 180 KDa

20   protein in lanes 1-6) and dimerisation (Fig 5, 390 KDa protein in lanes 2 and 6) of the PDGF beta receptor. When HR5 cells are first preincubated with MAb 2A1E2 and then with PDGF BB, dimerisation was inhibited at all the tested concentrations (Fig 5, Lanes 3, 4 and 5). This data indicates that binding of

25   MAb 2A1E2 on the receptor excludes ligand binding and receptor dimerisation.

Inhibition of Mitogenesis by MAb 2A1E2. As shown in Fig 6, MAb 2A1E2 inhibits PDGF BB-induced mitogenesis in human foreskin fibroblast AGO1523B cells in a concentration-dependent

30   manner, with maximum inhibition (69.55%) occurring at a concentration of 1.3 μM. When a non-inhibitory MAb, 4C5C8, was used, we did not detect significant inhibition of mitogenesis. Increasing the concentration of MAb 2A1E2 did not improve the degree of inhibition, primarily because these cells also

35   express PDGF alpha receptor (data not shown) which is not bound or inhibited by 2A1E2.

We also determined the effect of various concentrations of MAb 2A1E2 on primary smooth muscle cells from baboon artery. PDGF BB-mediated PDGF receptor phosporylation in baboon artery smooth muscle cells was inhibited by 200 nM and 20 nM MAb 2A1E2
5 (Fig. 7, Lanes 4 and 5, respectively).

As seen in Fig 8, 1 nM MAb 2A1E2 inhibits ^{3}H-thymidine incorporation in the presence of 1-2 ng/ml of PDGF BB by 90%, and 25 nM MAb inhibits mitogenesis by 80% at ligand concentrations ranging from 1-10 ng/ml. Concentrations of MAb
10 2A1E2 geater than 250 nM inhibit mitogenesis by 90% at all tested concentrations of ligand. When non-relevant MAbs are used there is no significant effect on mitogenesis in baboon smooth muscle cells.

In summary, we have disclosed a monoclonal antibody,
15 MAb 2A1E2, that is highly specific for the human PDGF beta receptor. MAb 2A1E2 inhibits the binding of PDGF to the human type beta PDGF receptor at nanomolar concentrations, and thus inhibits receptor activation as indicated by inhibition of ligand-mediated phosphorylation and dimerisation. The antibody
20 inhibits mitogenesis in vitro at micromolar concentrations. The proteolytic fragments of the MAb retain inhibitory function, as measured by the inhibition of ^{125}I-PDGF BB binding (Fig.3A). MAb 2A1E2 appears to recognise an epitope in the fifth Ig-like domain of the PDGF beta receptor (Fig 2), and
25 binding to this domain appears to prevent dimerisation of the receptor (Fig 5). There is a specific and significant inhibition of ligand-induced autophosphorylation of the PDGF beta receptor (Fig 4), at concentrations as low as 1.3 nM MAb 2A1E2. Consequently, we have found complete inhibition of PDGF
30 induced mitogenesis in HR5 cells (data not shown) at 0.1 μM MAb 2A1E2, and in human foreskin fibroblast cells (AGO1523B) 70% inhibition is achieved at 1 μM MAb 2A1E2 concentration.

MAb 2A1E2 was also tested for cross-reactivity with smooth muscle cells from baboon brachial artery. PDGF
35 BB-induced phosphorylation (Fig 7) and mitogenesis (Fig 8) was inhibited up to 80% by 20-25 nM MAb 2A1E2. Monoclonal antibody 2A1E2 does not cross-react with PDGF receptors from dog, rat,

mouse, or pig, and also does not cross-react with human type alpha PDGF receptor (data not shown).

It is of particular interest that, while we have demonstrated that MAb 2A1E2 binds to the fifth Ig-like domain of the PDGF type beta receptor and thus inhibits PDGF-mediated activity, PDGF binds to the third Ig-like domain.

It is to be understood that the above description is intended to be illustrative and not restrictive. Many embodiments will be apparent to those of skill in the art upon reviewing the above description. The scope of the invention should, therefore, be determined not with reference to the above description, but should instead be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled.

WHAT IS CLAIMED IS:

1.   A substantially purified immunoglobulin polypeptide that specifically binds to the fifth Ig-like domain of a human type beta platelet derived growth factor receptor (βPDGF-R), wherein binding of the polypeptide has one or more of the following effects:

      i)   inhibition of PDGF BB or AB binding to the βPDGF-R;

      ii)   inhibition of PDGF-induced βPDGF-R phosphorylation;

      iii)   inhibition of PDGF-induced dimerization of βPDGF-R;

      iv)   inhibition of PDGF-induced mitogenesis of cells displaying human βPDGF-R; and

      v)   inhibition of PDGF-induced chemotaxis and migration of cells displaying βPDGF-R.

2.   An immunoglobulin polypeptide of claim 1, wherein the polypeptide is a monoclonal antibody.

3.   An immunoglobulin polypeptide of claim 2, wherein the monoclonal antibody is antibody 2A1E2.

4.   A substantially purified polypeptide having an amino acid sequence substantially identical to a sequence of a complementarity determining region of an immunoglobulin polypeptide of claim 1.

5.   An immunoglobulin polypeptide of claim 1, wherein the polypeptide is linked to a detectable label.

6.   An immunoglobulin polypeptide of claim 1, wherein the polypeptide is chimeric.

7.   A substantially purified immunoglobulin polypeptide that specifically recognizes an epitope which lies

between amino acid residues 385-499 of the human type beta PDGF
receptor.

8.   A composition comprising a monoclonal antibody or
binding fragment thereof that binds to human type beta PDGF
receptor, which antibody or fragment inhibits _in vivo_ binding
of PDGF BB or AB to the receptor.

9.   An isolated nucleic acid having a sequence
substantially identical to a nucleic acid coding for an
immunoglobulin polypeptide or a binding fragment thereof,
wherein binding of the polypeptide or fragment to the fifth Ig-
like domain of a human type beta platelet-derived growth factor
receptor (βPDGF-R) has one or more of the following effects:
          i)   inhibition of PDGF BB or AB binding to the
receptor;
          ii) inhibition of PDGF-induced βPDGF-R
phosphorylation;
          iii) inhibition of PDGF-induced dimerization of
βPDGF-R; .
          iv) inhibition of PDGF-induced mitogenesis of
cells displaying the human βPDGF-R; and
          v)   inhibition of PDGF-induced chemotaxis and
migration.

10. A nucleic acid of claim 9, wherein the nucleic
acid is operably linked to a promoter.

11. A nucleic acid of claim 10, wherein the promoter
and the nucleic acid are contained in an expression vector.

12. A cell line transfected, transformed, or infected
with a nucleic acid of claim 9.

13. A method of producing a substantially purified
immunoglobulin polypeptide, or binding fragment thereof, which
specifically binds to the fifth Ig-like domain of a human type

beta PDGF receptor (βPDGF-R), wherein the binding of the immunoglobulin polypeptide to the βPDGF-R has one or more effects selected from the following group: inhibition of PDGF BB or AB binding to the receptor; inhibition of PDGF-induced βPDGF-R phosphorylation; inhibition of PDGF-induced βPDGF-R dimerization; and inhibition of PDGF-induced mitogenesis of cells displaying human βPDGF-R; and inhibition of PDGF-induced chemotaxis and migration of cells displaying human β-PDGF; the method comprising:

         i)   growing a cell line comprising a nucleic acid encoding the immunoglobulin polypeptide; and

         ii)   harvesting the immunoglobulin polypeptide.

14. A method of claim 13, wherein the cell line is a hybridoma.

15. A method of claim 14, wherein the hybridoma is ATCC no. HB10938.

16. A method of claim 13, wherein the immunoglobulin polypeptide is a monoclonal antibody.

17. A method of treating a human having a PDGF-mediated disease involving proliferation, migration or chemotaxis of smooth muscle cells, comprising administering to the patient a therapeutically effective dose of at least one immunoglobulin polypeptide selected from any one of claims 1, 7, and 8, or fragments of the immunoglobulin polypeptides, and a pharmaceutically acceptable carrier.

18. An isolated cell designated as ATCC no. HB10938.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US92/10359

A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) :Please See Extra Sheet.
US CL :424/85.8; 435/70.21, 172.2, 240.7; 530/387.1, 387.3, 388.1
According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 424/85.8; 435/70.21, 172.2, 240.7; 530/387.1, 387.3, 388.1

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, DIALOG: CA, WPI, MEDLINE, BIOSIS
search terms: PDGF, platelet derived growth factor, beta receptor, fifth domain, antibod?
